The Schwarzschild metric

The Schwarzschild metric is given by:

$$ds^2 = -\left(1 - \frac{2M}{r}\right) dt^2 + \frac{1}{1 - \frac{2M}{r}} dr^2 + r^2(d\theta^2 + \sin^2 \theta d\varphi),$$

while the flat metric is:

$$ds^2 = -dt^2 + dr^2 + r^2(d\theta^2 + \sin^2 \theta d\varphi).$$

where $c = G = 1$.

Tetrads: the Local Rest Frame

The *comoving* reference frame for spherically symmetric accretion is:

$$\hat{e}_t = u^\mu$$

$$\hat{e}_r = a^\mu / \sqrt{a^\nu a_\nu}$$

$$\hat{e}_\theta = (0, 0, 1/r, 0)$$

$$\hat{e}_\phi = (0, 0, 0, 1/(r \sin \theta)) .$$

This basis satisfies:

$$g_{\mu\nu} \hat{e}_{(\alpha)}^\mu \hat{e}_{(\beta)}^\nu = \eta_{(\alpha)(\beta)} .$$

The Local Rest Frame

The Local Rest Frame

The stress-energy tensor

The component $T^{\mu\nu}$ is the flux of μ -th component of the four-momentum p^μ through a surface of constant coordinate x^ν .
For an ideal fluid ($\eta = \xi = \kappa = 0$) in the Local Rest Frame:

$$T_{\text{ideal fluid}}^{\mu\nu} = \begin{bmatrix} \rho & & & 0 \\ & p & & \\ & & p & \\ 0 & & & p \end{bmatrix}_{\text{fid}},$$

where $\rho = \rho_0(1 + \varepsilon)$.

The radiation moments

$$w_0 = \int I \, d\Omega$$

radiation energy density

$$w_1 = \int I \cos \theta \, d\Omega$$

radiation energy flux

$$w_2 = \int I \left(\cos^2 \theta - \frac{1}{3} \right) d\Omega$$

radiation shear stress.

The radiation moments

The full stress-energy tensor

$$T^{\mu\nu} = T^{\mu\nu}_{\text{ideal fluid}} + \begin{bmatrix} w_0 & w_1 & 0 & 0 \\ w_1 & \frac{1}{3}w_0 + w_2 & 0 & 0 \\ 0 & 0 & \frac{1}{3}w_0 - \frac{1}{2}w_2 & 0 \\ 0 & 0 & 0 & \frac{1}{3}w_0 - \frac{1}{2}w_2 \end{bmatrix}_{\text{fid}}$$

The equations to solve are:

$$\nabla_\mu T^{\mu\nu} = 0 \quad 2 \text{ equations}$$

$$\nabla_\mu (\rho_0 u^\mu) = 0 \quad 1 \text{ equation}$$

moments of the photon transfer equation 2 equations.

Critical point

There is a critical point in the Euler equation at $v = v_s$:

$$(v^2 - v_s^2) \frac{(yv)'}{yv} - 2v_s^2 + \frac{M}{y^2 r} = -\frac{r}{yv(p + \rho)} ((\Gamma - 1)s_0 + vs_1).$$

where:

- y is the energy at infinity per unit rest mass,
- v is the velocity of the fluid,
- $v_s = \sqrt{\left(\partial p / \partial \rho\right)_s}$ is the adiabatic speed of sound,
- s_0 and s_1 are the source moments,
- Γ is the local adiabatic exponent.

Accretion efficiency

The Eddington luminosity is attained when the radiation pressure on a test electron-proton pair equals the gravitational pull on it:

$$\frac{L_{\text{Edd}}}{M} = \frac{4\pi c G m_p}{\sigma_T} \approx 3.27 \times 10^4 \frac{L_{\odot}}{M_{\odot}}.$$

In the numerical simulations we fix the accretion rate \dot{M} and calculate the luminosity $L = 4\pi r^2 w_1$.

We can adimensionalize these with the Eddington luminosity L_{Edd} and accretion rate $\dot{M}_{\text{Edd}} = L_{\text{Edd}}/c^2$: we define $l = L/L_{\text{Edd}}$ and $\dot{m} = \dot{M}/\dot{M}_{\text{Edd}}$.
